CHAPTER 7

Introduction to Recursion

And often enough, our faith beforehand in a certain result is the only thing that makes the result come true.

—William James, The Will to Believe, 1897

- 7.1 A simple example of recursion
- 7.2 The factorial function
- 7.3 The Fibonacci function
- 7.4 Checking palindromes
- 7.5 The binary search algorithm
- 7.6 Mutual recursion
- 7.7 Thinking recursively

Recursion

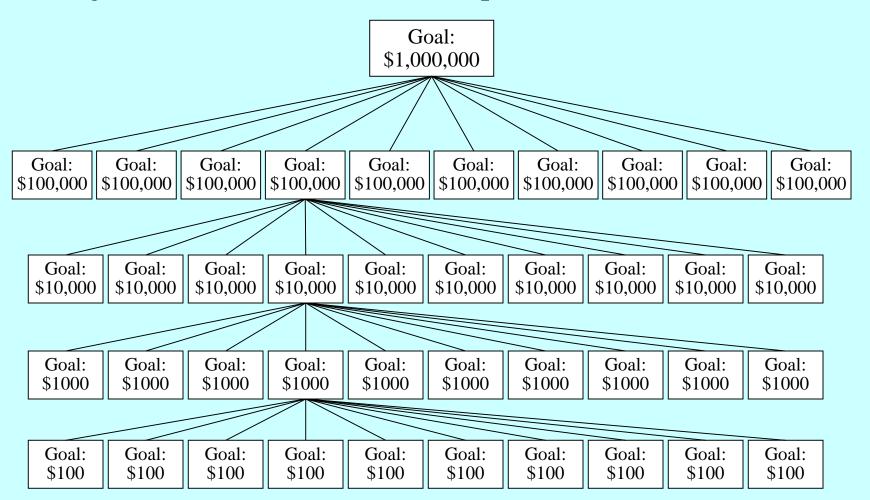

- One of the most important "Great Ideas" in this text is the concept of *recursion*, which is the process of solving a problem by dividing it into smaller subproblems *of the same form*. The italicized phrase is the essential characteristic of recursion; without it, all you have is a description of stepwise refinement.
- The fact that recursive decomposition generates subproblems that have the same form as the original problem means that recursive programs will use the same function or method to solve subproblems at different levels of the solution. In terms of the structure of the code, the defining characteristic of recursion is having functions that call themselves, directly or indirectly, as the decomposition process proceeds.

A Simple Illustration of Recursion

- Suppose that you are the national fundraising director for a charitable organization and need to raise \$1,000,000.
- One possible approach is to find a wealthy donor and ask for a single \$1,000,000 contribution. The problem with that strategy is that individuals with the necessary combination of means and generosity are difficult to find. Donors are much more likely to make contributions in the \$100 range.
- Another strategy would be to ask 10,000 friends for \$100 each. Unfortunately, most of us don't have 10,000 friends.
- There are, however, more promising strategies. You could, for example, find ten regional coordinators and charge each one with raising \$100,000. Those regional coordinators could in turn delegate the task to local coordinators, each with a goal of \$10,000, continuing the process reached a manageable contribution level.

A Simple Illustration of Recursion

The following diagram illustrates the recursive strategy for raising \$1,000,000 described on the previous slide:

A Pseudocode Fundraising Strategy

If you were to implement the fundraising strategy in the form of a C++ function, it would look something like this:

```
void collectContributions(int n) {
   if (n <= 100) {
      Collect the money from a single donor.
   } else {
      Find 10 volunteers.
      Get each volunteer to collect n/10 dollars.
      Combine the money raised by the volunteers.
   }
}</pre>
```

What makes this strategy recursive is that the line

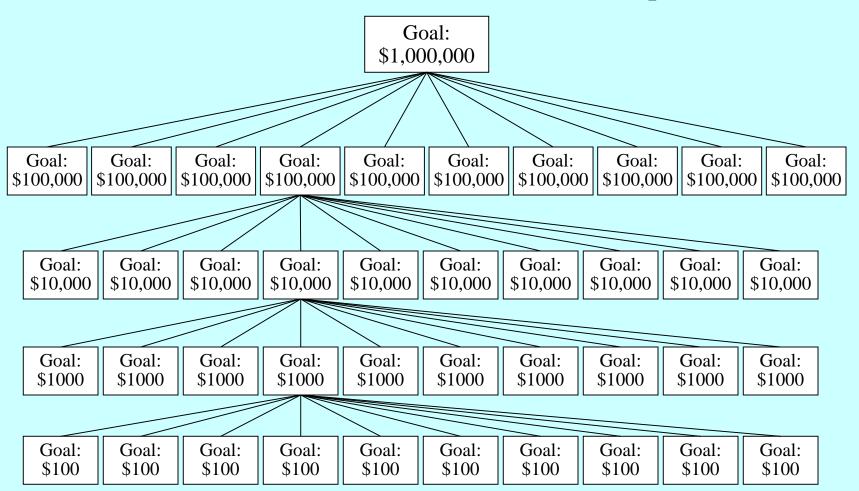

Get each volunteer to collect n/10 dollars.

will be implemented using the following recursive call:

```
collectContributions(n / 10);
```

A Simple Illustration of Recursion

Recursion tree for collectContributions(n) when n = 1,000,000: (Observe that this tree is 5 levels deep)

Recursive Functions

• The easiest examples of recursion to understand are functions in which the recursion is clear from the definition. As an example, consider the factorial function, which can be defined in either of the following ways:

$$n! = n \times (n-1) \times (n-2) \times \dots \times 3 \times 2 \times 1$$

$$n! = \begin{cases} 1 & \text{if } n \text{ is } 0 \\ n \times (n-1)! & \text{otherwise} \end{cases}$$

• The second definition leads directly to the following code, which is shown in simulated execution on the next slide:

```
int fact(int n) {
   if (n == 0) {
      return 1;
   } else {
      return n * fact(n - 1);
   }
}
```

Simulating the fact Function

```
int main() {
 int fact(int n) {
  int fact(int n) {
    int fact(int n) {
     int fact(int n) {
      int fact(int n) {
       int fact(int n) {
           if (n == 0) {
             return 1;
           } else {
             return n * fact(n - 1);
                                                      n
```

```
RecursiveFactorial

Enter n: 5
5! = 120
```

The Recursive "Leap of Faith"

- The purpose of going through the complete decomposition of the factorial function is to convince you that the process works and that recursive calls are in fact no different from other method calls, at least in their internal operation.
- The danger with going through these details is that it might encourage you to do the same when you write your own recursive programs. As it happens, tracing through the details of a recursive program almost always makes such programs harder to write. Writing recursive programs becomes natural only after you have enough confidence in the process that you don't need to trace them fully.
- As you write a recursive program, it is important to believe that any recursive call will return the correct answer as long as the arguments define a simpler subproblem. Believing that to be true—even before you have completed the code—is called the *recursive leap of faith*.

The Recursive Paradigm

• Most recursive methods you encounter in an introductory course have bodies that fit the following general pattern:

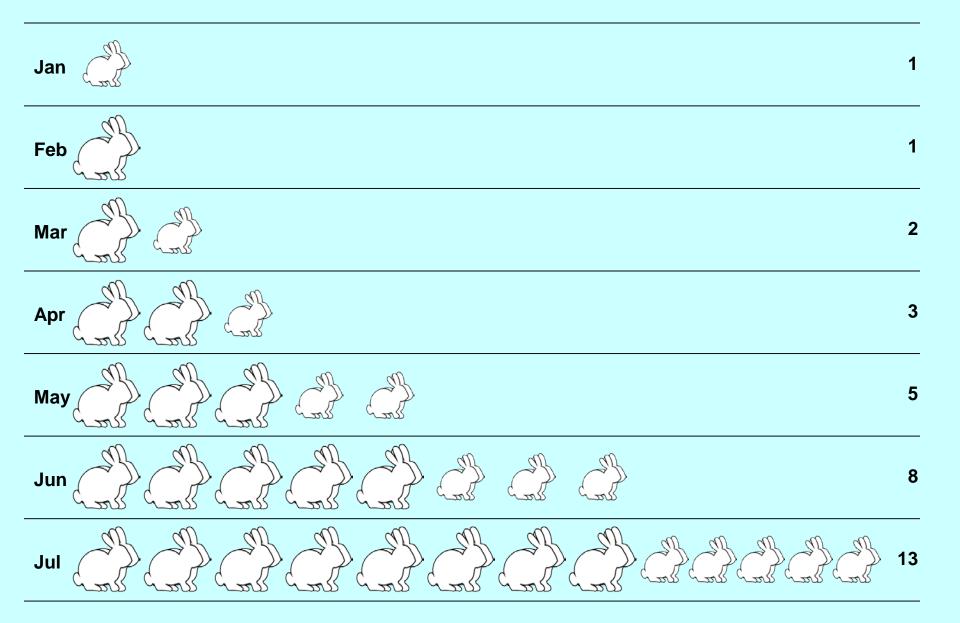

```
if (test for a simple case) {
    Compute and return the simple solution without using recursion.
} else {
    Divide the problem into one or more subproblems that have the same form.
    Solve each of the problems by calling this method recursively.
    Return the solution from the results of the various subproblems.
}
```

- Finding a recursive solution is mostly a matter of figuring out how to break it down so that it fits the paradigm. When you do so, you must do two things:
 - 1. Identify *simple cases* that can be solved without recursion.
 - 2. Find a *recursive decomposition* that breaks each instance of the problem into simpler subproblems of the same type, which you can then solve by applying the method recursively.

The Fibonacci Function

- In 1202, the Italian mathematician Leonardo Fibonacci published a treatise entitled *Liber Abaci* in which he argued for the adoption of the Hindu-Arabic numbering system over the far more cumbersome system of Roman numerals still in use at the time.
- As one of the examples in *Liber Abaci*, Fibonacci asked a question about the growth pattern in a population of rabbits under the following, admittedly fanciful assumptions:
 - Rabbit pairs become fertile two months after their birth.
 - Fertile rabbit pairs produce a new pair every month.
 - Old rabbits never die but keep on reproducing.
- The sequence of values recording the population of rabbits turns up in a surprising number of contexts and is called the *Fibonacci sequence*.

Fibonacci's Rabbits

Recursive Formulation of fib(n)

• The n^{th} term in the Fibonacci sequence has the following recursive definition:

fib(n) =
$$\begin{cases} n & \text{if n is 0 or 1} \\ \text{fib(n-1) + fib(n-2)} & \text{otherwise} \end{cases}$$

• As with factorial, the recursive definition leads directly to an implementation, as follows:

```
int fib(int n) {
   if (n < 2) {
      return n;
   } else {
      return fib(n - 1) + fib(n - 2);
   }
}</pre>
```

Exercise: Greatest Common Divisor

One of the oldest known algorithms that is worthy of the title is Euclid's algorithm for computing the greatest common divisor (GCD) of two integers, x and y. Euclid's algorithm is usually implemented iteratively using code that looks like this:

```
int gcd(int x, int y) {
   int r = x % y;
   while (r != 0) {
      x = y;
      y = r;
      r = x % y;
   }
   return y;
}
```

Rewrite this method so that it uses recursion instead of iteration, taking advantage of Euclid's insight that the greatest common divisor of x and y is also the greatest common divisor of y and the remainder of x divided by y.

Solution: A Recursive GCD Function

```
int gcd(int x, int y) {
   if (x % y == 0) {
      return y;
   } else {
      return gcd(y, x % y);
   }
}
```

As is usually the case, the key to solving this problem is finding the recursive decomposition and defining appropriate simple cases.

Palindromes

- Recursion is not limited to numeric examples and appears naturally in many other contexts. For example, a string is a palindrome if one of the two following cases applies:
 - It is empty or contains a single character.
 - Its first and last characters match and enclose a palindrome.
- This decomposition gives rise to the following code:

Linear Search

- The simplest strategy for searching is to start at the beginning of the array and look at each element in turn. This algorithm is called *linear search*.
- Linear search is straightforward to implement, as illustrated in the following method that returns the first index at which the value key appears in array, or -1 if it does not appear at all:

```
int linearSearch(int key, Vector<int> array) {
   for (int i = 0; i < array.size(); i++) {
      if (key == array[i]) return i;
   }
   return -1;
}</pre>
```

Searching for Area Codes

- To illustrate the efficiency of linear search, it is useful to work with a somewhat larger example.
- The example on the next slide works with an array containing many of the area codes assigned to the United States.
- The specific task in this example is to search this list to find the area code for the Silicon Valley area, which is 650.
- The linear search algorithm needs to examine each element in the array to find the matching value. As the array gets larger, the number of steps required for linear search grows in the same proportion.
- As you watch the slow process of searching for 650 on the next slide, try to think of a more efficient way in which you might search this particular array for a given area code.

Linear Search (Area Code Example)

| 264 | 265 | 266 | 267 | 268 | 269 | 270 | 271 | 272 | 273 | 274 | 275 | 276 | 277 | 278 | 279 | 280 | 281 | 282 | 283 | 284 | 285 |

The Idea of Binary Search

- The fact that the area code array is in ascending order makes it possible to find a particular value much more efficiently.
- The key insight is that you get more information by starting at the middle element than you do by starting at the beginning.
- When you look at the middle element in relation to the value you're searching for, there are three possibilities:
 - If the value you are searching for is greater than the middle element,
 you can discount every element in the first half of the array.
 - If the value you are searching for is less than the middle element, you can discount every element in the second half of the array.
 - If the value you are searching for is equal to the middle element, you can stop because you've found the value you're looking for.
- You can repeat this process on the elements that remain after each cycle. Because this algorithm proceeds by dividing the list in half each time, it is called *binary search*.

Binary Search (Area Code Example)

Binary search needs to look at only eight elements to find 650.

Mutual Recursion

- In some cases, recursive processes involve more than a single function. Instead, one function calls another, which calls another, which eventually circles back around to the original function. Such situations are called *mutual recursion*.
- The text uses the following simple example to illustrate mutual recursion:

```
bool isEven (unsigned int n) {
   if (n == 0) return true;
   else return isOdd(n - 1);
}

bool isOdd (unsigned int n) {
   if (n == 0) return false;
   else return isEven(n - 1);
}
```

Thinking Recursively

- Writing recursive programs requires developing a new way of thinking about problems that focuses more on a holistic view of the problem than on the details.
- The following checklist may prove helpful:
 - Does your implementation begin by checking for simple cases?
 - Have you solved the simple cases correctly?
 - Does your recursive decomposition make the problem simpler?
 - Does the simplification eventually reach the simple cases?
 - Do the recursive calls in your function represent subproblems that are truly identical in form to the original?
 - Do the solutions to the recursive subproblems provide a complete solution to the original problem?

The End
